The physico-chemical interaction in the Tl₂Se–SnSe–PbSe quasiternary system was investigated by differential thermal analysis and X-ray diffraction in combination with mathematical modeling. Diagrams of the phase interaction, the projection of the liquidus surface and an isothermal section (520 K) were constructed. The quasiternary system is of the invariant eutectic type. The three-dimensional one-, two- and three-phase regions present in the Tl₂Se–SnSe–PbSe system are described.

Introduction

The Tl₂Se–SnSe–PbSe quasiternary system was investigated by Guseinov et al. [1]. However, the authors did not take into consideration the formation in the Tl₂Se–Sn(Pb)Se system of the ternary compounds Tl₄SnSe₃ and Tl₄PbSe₃, which melt congruently [2-6]. The two ternary compounds are isostructural, which indicates high probability of formation of a solid solution. The good thermoelectric properties of Tl₄SnSe₃ and Tl₄PbSe₃ provide the motivation for an investigation of the character of the physico-chemical interaction in the Tl₂Se–SnSe–PbSe quasiternary system.

Experimental

Binary thallium(I), tin(II) and lead(II) selenides were prepared from stoichiometric amounts of high-purity elements (99.99 wt.%) in evacuated quartz containers. The ternary compounds Tl₂SnSe₃ and Tl₂PbSe₃ were obtained from stoichiometric amounts of binary Tl₂Se, SnSe and PbSe. The multicomponent alloys were synthesized by the direct single-temperature method from binary and ternary selenides in quartz ampoules, which were evacuated to a residual pressure of 0.13 Pa. The highest synthesis temperature was 1023 K. After thermal treatment at the highest temperature for 24-36 h the samples were slowly cooled down (20-30 K per hour) to 520 K and homogenized at this temperature for 168 h. Subsequently the ampoules were quenched in cold water. The phase equilibria were studied by differential thermal analysis (DTA) and X-ray powder diffraction in combination with the simplex method of mathematical modeling of phase equilibria in multicomponent systems. The differential thermal analysis was carried out by means of a device that includes an x-y recorder PDA-1 and a chromel-alumel combined thermocouple (the linearity of heating and cooling was controlled by a RIF-101 programmer) with an accuracy of ±5 K. X-ray powder diffraction was carried out on a DRON-4 diffractometer (Cu Kα radiation, Ni filter). The simplex method of computer simulation of phase equilibria has been described by Barchiy [7].

Results and discussion

Initially, we carried out a triangulation of the Tl₂Se–SnSe–PbSe quasiternary system [8,9] on the basis of literature data [10]. The SnSe–PbSe system is characterized by a eutectic invariant interaction. Ternary complex compounds form in the Tl₂Se–SnSe(PbSe) binary systems: the phases Tl₂SnSe₃ and Tl₂PbSe₃ melt congruently at 708 K and 808 K, respectively, Tl₂Sn₂Se₃ melts incongruently at 683 K by the reaction L + lt-SnSe ↔ Tl₂Sn₂Se₃, and decomposes according to Tl₂Sn₂Se₃ ↔ Tl₂SnSe₃ + lt-SnSe₂ at low temperature (640 K) [3,5]. Using the results of XRD and the method developed by Gurtler we conclude that Tl₂SnSe₃–Tl₂PbSe₃ and PbSe–Tl₂SnSe₃ are quasibinary sections, which divide the Tl₂Se–SnSe–PbSe system into separate subsystems.

The Tl₂SnSe₃–Tl₂PbSe₃ system belongs to the Roozeboom type IV (Fig. 1). The lines of primary
crystallization of the alloys on the bases of \( \varepsilon \) (\( \text{Tl}_4\text{SnSe}_3 \)) and \( \eta \) (\( \text{Tl}_4\text{PbSe}_3 \)) crystals cross at an invariant point with the coordinates 62 mol.% \( \text{Tl}_4\text{PbSe}_3 \), 754 K (peritectic process \( L + \eta \leftrightarrow \varepsilon \)). Limited solid solutions \( \varepsilon \) (based on \( \text{Tl}_4\text{SnSe}_3 \)) and \( \eta \) (based on \( \text{Tl}_4\text{PbSe}_3 \)) are formed in the system. At the temperature of 520 K the regions of the \( \varepsilon \)- and \( \eta \)-solid solutions do not exceed 48 and 15 mol.%, respectively.

The \( \text{PbSe}–\text{Tl}_4\text{SnSe}_3 \) system belongs to the Roozeboom type V (Fig. 2) and is characterized by the formation of limited solid solutions \( \delta \) (based on \( \text{PbSe} \)) and \( \varepsilon \) (based on \( \text{Tl}_4\text{SnSe}_3 \)). The liquidus of the quasibinary system consists of two lines of primary crystallization, which intersect at an invariant point with the coordinates: 12 mol.% \( \text{PbSe} \), 690 K (eutectic process \( L \leftrightarrow \delta + \varepsilon \)). The extents of the \( \delta \)- and \( \varepsilon \)-solid solutions at the eutectic temperature are 9 and 22 mol.% respectively; at the temperature 520 K they are 7 and 15 mol.% respectively.

Forty-two alloys were prepared for the investigation of the \( \text{Tl}_2\text{Se}–\text{SnSe}–\text{PbSe} \) quasiternary system. The compositions of the alloys were selected so that they are located along the quasibinary sections \( \text{Tl}_4\text{SnSe}_3–\text{Tl}_4\text{PbSe}_3 \), \( \text{PbSe}–\text{Tl}_4\text{SnSe}_3 \), in the homogeneity regions of the binary and ternary compounds (for plotting the isothermal section), and on the simplex points (for the mathematical computer simulation of the projection of the liquidus surface on the concentration triangle).
Based on the XRD results the isothermal section at 520 K of the Tl$_2$Se–SnSe–PbSe quasiternary system was plotted (Fig. 3). Limited solid solutions are formed in the ternary system: γ based on lt-SnSe, δ based on PbSe, η based on Tl$_4$PbSe$_3$, ε based on Tl$_4$SnSe$_3$. Due to the solid-phase decomposition of Tl$_2$Sn$_2$Se$_3$ at 640 K, only reflections of the δ-, ε-, and γ-phases are present in the diffraction patterns of the alloys in the PbSe–Tl$_2$Sn$_2$Se$_3$–SnSe subsystem at 520 K.

The width of the solid solution on the basis of lt-SnSe (γ-phase) does not exceed 3 mol.% along the Tl$_2$Se–SnSe section and 18 mol.% in the SnSe–PbSe system. The largest areas of homogeneity correspond to the solid solutions ε based on Tl$_4$SnSe$_3$ and Tl$_2$Se (to 37 mol.% in the Tl$_2$Se–SnSe system, to 48 mol.% along the Tl$_2$SnSe$_3$–Tl$_4$PbSe$_3$ section, and to 7 mol.% along the PbSe–Tl$_2$SnSe$_3$ section), η based on Tl$_4$PbSe$_3$ and Tl$_2$Se (to 35 mol.% in the Tl$_2$Se–PbSe system and to 15 mol.% along the Tl$_2$SnSe$_3$–Tl$_4$PbSe$_3$ section), and δ on the basis of binary PbSe (to 10 mol.% in the Tl$_2$Se–PbSe system, to 23 mol.% in the SnSe–PbSe system, and to 15 mol.% along the PbSe–Tl$_2$SnSe$_3$ section).

The projection of the liquidus surface of the Tl$_2$Se–SnSe–PbSe quasiternary system (Fig. 4) on the concentration triangle was constructed according to the results of the DTA investigation and computer simulation of the phase equilibria in multicomponent systems by the simplex triangle. It consists of six fields of primary crystallization: δ-crystals (PbSe–e1–E1–e4–E2–U2–U1–e3–PbSe), η-crystals (Tl$_4$PbSe$_3$–Tl$_2$Se–p2–E1–e1–Tl$_4$PbSe$_3$), ε-crystals (Tl$_4$SnSe$_3$–e2–E2–c4–E1–p2–Tl$_2$Se–Tl$_2$SnSe$_3$), γ-crystals on the basis of Tl$_2$Sn$_2$Se$_3$ (p1–U2–E2–c2–p1), γ-crystals on the basis of lt-SnSe (m–U1–U2–p1–m) and β-crystals on the basis of ht-SnSe (SnSe–e3–U1–m–SnSe). The fields of primary crystallization are delimited by 11 monovariant eutectic and peritectic lines. The types and temperatures of the processes in the Tl$_2$Se–SnSe–PbSe quasiternary system are listed in Table 1. The monovariant lines cross at two invariant peritectic and two invariant eutectic points:

U1: L + ht-SnSe ↔ PbSe + lt-SnSe, 39 mol.% Tl$_2$Se, 50 mol.% SnSe, 11 mol.% PbSe, 725 K;
U2: L + lt-SnSe ↔ Tl$_2$Sn$_2$Se$_3$ + PbSe, 44 mol.% Tl$_2$Se, 12 mol.% SnSe, 42 mol.% PbSe, 673 K;
E1: L ↔ Tl$_4$SnSe$_3$ + PbSe + Tl$_2$Sn$_2$Se$_3$, 60 mol.% Tl$_2$Se, 15 mol.% SnSe, 25 mol.% PbSe, 657 K;
E2: L ↔ Tl$_2$Sn$_2$Se$_3$ + PbSe + Tl$_2$Sn$_2$Se$_3$, 48 mol.% Tl$_2$Se, 38 mol.% SnSe, 14 mol.% PbSe, 647 K.

No new compounds were observed in the Tl$_2$Se–SnSe–PbSe quasiternary system.

**Conclusions**

Differential thermal analysis, X-ray diffraction and mathematical simulation of phase equilibria in multicomponent systems by the simplex method were used to investigate the physico-chemical interaction in the Tl₂Se–SnSe–PbSe system for the first time. The character of the monovariant processes and the coordinates of the invariant processes were determined. The existence of solid solutions of the ternary compounds Tl₄SnSe₃ and Tl₄PbSe₃ was established. No new compounds were observed in the quasiternary system. The results of the investigation may be used for the synthesis of new thermoelectric materials for semiconductor technology.
